HIV/AIDS Survey in Southern Angola

Deminers in Angola have a higher than average risk for HIV infection and transmission as a result of their work in border areas and their high mobility. The Demining HIV/AIDS Partnership conducted a survey to explore deminers’ HIV/AIDS knowledge in Cassinga, southern Angola. Among other conclusions, the results stressed the need for an increase in HIV/AIDS education.

The necessary mobility of deminers across Angola may increase the spread of HIV/AIDS across a country with a low HIV-prevalence rate. This survey, conducted by the Demining HIV/AIDS Partnership in 2011, explores the HIV/AIDS-related knowledge, attitudes, behaviors and perceptions among deminers in southern Angola. The Demining HIV/AIDS Partnership is a coalition of international HIV/AIDS non-governmental organizations comprised of the Demining HIV/AIDS Service Foundation (South Africa) and the Organization of Natural Humanitarian Aid (Angola). The survey was conducted with the intention of stimulating evidence-based HIV/AIDS strategies targeting the landmine clearance sector and landmine-impacted communities around the world. The survey provides interesting and useful details about how lack of HIV knowledge leads to misconceptions and fear of people living with HIV, often resulting in stigma and discrimination. The results also provide key information regarding the interviewed deminers’ understanding of HIV/AIDS, and in which ways their understanding (or lack thereof) affects their attitudes and behavior, including sexual associations while on demining contracts and attitudes toward HIV, HIV testing and people living with HIV.

According to the U.S. Agency for International Development, “The countries of Southern Africa have some of the highest HIV prevalence rates in the world, and the region remains the global epicenter of the epidemic.” According to the Joint United Nations Programme on HIV/AIDS (UNAIDS), nine countries in Southern Africa continue to bear a disproportionate share of the global AIDS burden: All except Angola have an HIV prevalence greater than 10 percent and have some of the highest HIV prevalence rates in the world.”

Issues relating to HIV/AIDS and deminers have international dimensions, which are reinforced by the Interagency Coalition on AIDS and Development’s observations and recommended intervention programs for the sector published in a fact sheet in 2002–2003. In Mozambique, the Accelerated Demining Programme claims it lost 10 deminers to HIV/AIDS, but only one deminer to a mine accident.

Relatedly, the labor laws in some countries, such as Mozambique, reveal the legal difficulties that demining companies face regarding HIV tests. In June 2005, the Ministry of Public Administration, Labour and Social Security fined the U.S.-based demining company RONCO Consulting Corporation after discovering that RONCO required Mozambican sappers to take HIV tests when selecting them for a demining mission to Afghanistan.

Demining and AIDS in Angola

The well-developed landmine clearance sector in Angola employs local and international deminers. Decades of war in Angola, from the 1970s to 2002, left an estimated 20 million landmines in Angolan soil. Norwegian People’s Aid, Menschen gegen Minen (People Against Landmines), The HALO Trust, MAG (Mines Advisory Group), DanChurch Aid, Handicap International, Santa Barbara and other agencies trained thousands of deminers in Angola over the past two decades. The Instituto Nacional de Desminagem (National Institute of Demining) in Angola, supported by the United Nations Development Programme, trains thousands of Angolans in manual demining, mine detection dog handling and mechanical-demining support-asset skills at the INAD School in Luanda. Angola has thousands of deminers removing landmines across the country. Clearance efforts are priorities in all of Angola’s 18 provinces.

As a result of clearance needs, deminers are a highly mobile population. Angolan deminers are vulnerable to HIV infection and are in turn a potential vector of HIV transmission. According to the International Organization for Migration, “… mobile populations in general—have played a significant role in the initial spread of HIV in the southern African region. The largely seasonal or temporary character of migration in southern Africa, with migrants returning home to their families on a regular basis, has facilitated the rapid spread of the virus. However, the fact that population movement distributes HIV has become less relevant in the current stage of the AIDS epidemic in southern Africa (with extremely high HIV prevalence levels in the population in general). Migrants are no longer agents that help to spread HIV, but have become individuals at high risk. Several studies have shown that migrants are more vulnerable to HIV infection than their non-migrant counterparts.”

USAID further explains the situation: "With an estimated 2 percent of the adult population living with HIV, Angola has one of the lower HIV prevalence rates in sub-Saharan Africa. … Since the war, however, movement has become less restricted, and the likelihood of HIV reaching once-isolated communities has increased… Data collected from women attending antenatal clinics suggests the intensity of the HIV epidemic varies among Angola’s different provinces, with the highest rates of infection occurring in the areas bordering Namibia, along the transport route to Luanda, and along the border of the Democratic Republic of the Congo; the lowest rates are found in the center of the country.”

Methodology

To examine the HIV/AIDS realities and risks to deminers in Angola, the Demining/AIDS/HIV Partnership conducted a targeted survey. The survey included 45 in-depth interviews with deminers in Cassinga in southern Angola. All respondents were male Angolan deminers employed by Vanguard Demining Services on the Tchamutete Demining Project in the Huila province. The interviews were conducted at the VDS Tchamutete Base Camp in a six-week period from August to October 2011. All interviews were conducted in Portuguese, and each interview took approximately three hours to complete. Joao Artur Dumba translated the research tool and the survey responses into English.

Demographics

The respondents were between the ages 20 and 49 and self-identified as sexually active. They came from the Benguela, Cunene, Huila, Kuando Kubango, Kwanza Sul and Malanje provinces. The following shows the respondents’ education:

- 67 percent of the deminers received at least eight years of primary school education.
- 21 percent received more than eight years of primary school education.
- 12 percent said they had never attended school.

The mean duration of demining work experience in the survey population was eight years. Over the past five years, 31 of the deminers said they spent nine months each year living in demining camps, and 14 deminers reported that they lived in camps for at least six months each year. All respondents lived in tents, returning home once every three months for two weeks. Their work conditions did not allow their spouses to visit. All 45 respondents also said they would opt out of demining if alternative, closer-to-home opportunities arose.

**Methodology**

To examine the HIV/AIDS realities and risks to deminers in Angola, the Demining/AIDS/HIV Partnership conducted a targeted survey. The survey included 45 in-depth interviews with deminers in Cassinga in southern Angola. All respondents were male Angolan deminers employed by Vanguard Demining Services on the Tchamutete Demining Project in the Huila province. The interviews were conducted at the VDS Tchamutete Base Camp in a six-week period from August to October 2011. All interviews were conducted in Portuguese, and each interview took approximately three hours to complete. Joao Artur Dumba translated the research tool and the survey responses into English.
HIV testing and stigma. Of those interviewed, 32 said they had HIV tests in the past, were prepared to take regular HIV tests and would encourage their sexual partners to test for HIV as well. Detoured by fear of what their sexual history could mean for HIV test results and the stigmas and responsibilities that come with a positive result, 12 deminers said they had not taken HIV tests in the past. All of the interviewed deminers said they would visit a health center for advice if they suspected they became HIV-infected.

Seven deminers said they would separate from a sexual partner exhibiting AIDS symptoms, while 25 said they would continue with the relationship but advise their partner to visit a health center. Slightly more than one-third, 17 deminers, said they would abandon sexual relationships with a partner if HIV test results are discordant, while 28 said they would seek advice from health centers. Twenty-nine of the deminers accept HIV/AIDS-infected people as normal, while 16 said HIV-positive people should be avoided. Twenty-one of the deminers said they discuss HIV/AIDS issues with their families; 24 said they do not.

Analysis. The responses reveal that deminers would prefer to work closer to home. However, due to limited employment options, they are compelled to continue with this trade. Almost all surveyed deminers admitted having sexual partners while on demining contracts. The history of STIs in 66 percent of the study population adds up to a high-risk HIV transmission scenario. Persons with STIs are more susceptible to HIV infection and are more likely than uninfected persons to spread HIV to their sexual partners. The majority of deminers admitted to earning sufficient funds, making possible the purchase of sexual partners. The majority, 72 percent of the deminers, said they would avoid HIV/AIDS-affected persons, stigmatization of HIV/AIDS and of the positive HIV state among deminers is reflected in broader Angolan society: “A 2003 KAP [knowledge, attitudes and practices] study reported nearly half of all young people (and more than two-thirds of those with no education) said they would refuse to share a meal with an HIV-positive person. According to the 2005–2006 KAP study, 80 percent of youth interviewed showed some discriminatory tendencies toward HIV-positive individuals.”

All respondents said they were circumcised through cultural initiation rites. The deminers reported their marital status as follows:

- 28 had one wife.
- 6 had two wives.
- 2 had three wives.
- 4 were single.

Six deminers said they had no sexual partners outside marriage, 36 deminers had one regular sexual partner outside marriage and three said they had at least two regular sexual partners outside marriage. Nearly all (43) of the 45 interviewed deminers said they had sexual partners while on demining contracts. Two respondents said they never had sexual partners while on demining contracts. More than half, 28 deminers, said they had a sexually transmitted infection previously.

Results

Basic HIV/AIDS knowledge. All interviewed deminers confirmed that HIV and AIDS exist, and all respondents said that no treatment exists for AIDS. The following shows the breakdown of responses when asked about the transmission of HIV/AIDS:

- 21 deminers said that HIV is transmitted through sex.
- 37 said it is transmitted through blood transfusion.
- 15 said through sex without a condom.
- 6 believed that kissing and touching transmit HIV.
- 27 said barber shops, needles and sharps transmit HIV.
- 4 deminers could not mention a single method of HIV transmission.
- 2 deminers mentioned mother-to-child HIV transmission.
- All stated that prolonged coughing, diarrhea, weight loss and hair changes are AIDS symptoms.
- The respondents identified these high-risk groups:
  - 37 deminers said prostitutes are the biggest HIV/AIDS risk group.
  - 40 deminers cited youths, foreigners and truck drivers as HIV vulnerable groups.
  - 4 deminers said everyone is equally vulnerable to HIV infection.

The deminers reported their sources for HIV/AIDS information:

- 42 mentioned both the Angolan media and health centers.
- 20 confirmed receiving HIV/AIDS information at the demining workplace.

- 25 said they had never received HIV/AIDS information at the demining workplace.

Deminers’ attitudes toward HIV prevention, testing and stigma. To prevent HIV infection, the respondents listed the following actions:

- 41 of the 45 deminers said they prevent HIV infection by always using condoms when having sex with non-regular partners.
- 4 said they do not use condoms.
- 2 said they abstain from sex when they are not with their wives.
- 4 said they prevent HIV through being faithful to their wives and regular partners.
- 6 said they avoid sleeping with prostitutes.

The majority, 43 of the deminers, said they get condoms from health centers, 37 said they buy condoms from shops, six said they get them from their partners. Two deminers said they get condoms from the demining workplace.

Regarding other HIV transmission methods, 28 deminers said they do not share shaving kits. Most, 39 of the 45 deminers interviewed, said they had evacuated a landmine-affected colleague in the past. All deminers involved said they had not worn gloves during the casualty evacuation process.
The demining workplace has insufficient HIV/AIDS pre-exhibits traits characteristic of a high-risk HIV group. which are often invisible and inaccessible to the public-

HIV/AIDS Facts

- HIV is a virus that attacks the immune system. AIDS is a syndrome where the body has a reduced ability to fight infection and disease.
- HIV cannot be transmitted by touching another infected person or through kissing, unless one or both people has an open mouth sore that is bleeding.
- HIV can be transmitted through interchange of blood or bodily fluids with an HIV infected person, primarily in cases of:
  - Unprotected sex (vaginal, anal or oral)
  - Sharing needles with other people
  - Transmission between mother and child during pregnancy, childbirth or nursing
  - 34 million people live with HIV in the world
- There are therapy programs that can stop HIV virus from reproducing in the body.

Conclusion

According to USAID, "Other conditions that increase the risk of continuing the spread of the virus in Angola include mobility among the 4 million people currently internally displaced by the war; high levels of civilian contact with military personnel; low levels of education; extreme poverty; limited female autonomy; weak social networks and public services; and cross-border interaction with Namibia and Zambia, where HIV prevalence rates are 13.1 percent and 13.5 percent, respectively, according to UNAIDS." This study attempted to identify an occupation that exhibits traits characteristic of a high-risk HIV group. The demining workplace has insufficient HIV/AIDS prevention and education services for deminers. Deminers need continuous education on safe sexual practices, and demining companies must deliver HIV/AIDS services to their workers and local communities. HIV/AIDS hot spots emerging in Angola are illustrated in Figure 3 on page 36.

Reprinted with permission from Demining HIV/AIDS Partnership. The authors appreciate the permission and support they received from Vanguard Demining Services Project Manager Johannes Van Schalkwyk and Technical Adviser Johan Strydom to conduct the survey. They would like to thank the deminers who participated in the survey for their consent and for the time donated by Faririsai Berejena, Demining Supervisor Joao Bango, Dr. Tamuka Chirowonzi (Elizabeth Glaser Pediatric AIDS Foundation), Dr. Desire Manganya (Zagpo-Brazil), Dr. Silence Gave (Zimplats), Dr. Pongeni Dikuyo (Centers for Disease Control) and Kintossi Dimingo for giving valued advice on the study.
